Engine Bearing Failure Analysis. Engine bearings depend on a film of oil to keep shaft and bearing surfaces separated (figure A). Bearings fail when the oil film breaks down or when the bearing is overloaded. The oil film is generated by shaft rotation (figure B). At rest, the shaft and bearing are in contact.

Metal failure is a common phenomenon when a metal component is subjected to cyclic stresses or overloading. In this article we discuss how to perform a metal fatigue failure analysis to determine the reason for the failure. By this we can be able to take necessary corrective action in design, maintenance, and operation to avoid another failure.

Metal Failure Analysis & Steps to Investigate the Failure

A contained engine failure is one in which components might separate inside the engine but either remain within the engine's cases or exit the engine through the tail pipe. An uncontained engine event occurs when an engine failure results in fragments of rotating engine parts penetrating and exiting through the engine case.

A complete lack of lubrication in the crankcase usually leads to seizure of the bearing and total failure of the engine. But, experts say a more frequent issue regarding lubrication is simply inadequate oiling. The absence of a proper oil film will result in metal-to-metal contact, occasionally to just one bearing or often to a number of them.
