A model based upon lubrication and thin airfoil theories permits steady periodic waves on the surface of a thin inclined layer of viscous fluid, when an upward stream of air flows over its surface. The flow in the layer is rotational, and is sustained by a balance between the lubrication force in the fluid and a surface shear and pressure gradient supplied by the airflow over it.

We study both experimentally and theoretically the classical problem of the circular hydraulic jump. By means of elementary hydrodynamics we investigate the scaling laws governing the position of the hydraulic jump and compare our predictions with experimental data. The results of our simple model are in good agreement with the experiments and with more elaborate approaches.
